

**Problem 1)**

Consider the classical Lagrangian densities for the following relativistic quantum field theories,

$$\mathcal{L}_Y = \frac{i}{2} \bar{\psi} \overleftrightarrow{\not{D}} \psi - M \bar{\psi} \psi + \frac{1}{2} (\partial\phi)^2 - \frac{1}{2} m_s^2 \phi^2 - g \bar{\psi} \psi \phi - \frac{\lambda_1}{3!} \phi^3 - \frac{\lambda_2}{4!} \phi^4 \quad (1)$$

$$\mathcal{L}_V = \frac{i}{2} \bar{\psi} \overleftrightarrow{\not{D}} \psi - M \bar{\psi} \psi - \frac{1}{4} F^{\mu\nu} F_{\mu\nu} + \frac{m_V^2}{2} A^\mu A_\mu - g \bar{\psi} \not{A} \psi. \quad (2)$$

We could envision each of these being proposed as models of the interactions between spinor “nucleons” of mass  $M$  represented by the Fermi field  $\psi$ . In the first case, the interaction is then mediated by a scalar “pion” field  $\phi$  with mass  $m_s$ , and in the second it is mediated by a vector field  $A^\mu$  with mass  $m_V$ . As usual, the field strength tensor  $F^{\mu\nu} = \partial^\mu A^\nu - \partial^\nu A^\mu$ . (Note that to be realistic we should really have pseudoscalar and vector interactions.) In the second theory, we would get the Maxwell field if we set  $m_V = 0$ .

- (a) Use the fast mnemonic that we developed in class for translating a classical Lagrangian density into QFT Feynman rules to write down all the Feynman rules for the two theories above. Make a comment about where each factor of “ $i$ ” comes from. Use straight lines for  $\psi$ , dashed lines for  $\phi$ , and wavy lines for  $A^\mu$ .
- (b) Draw a two-loop diagram for the vector field case. Draw an example of a diagram that would give problems if you have not worried about the “reduction” of external leg states.
- (c) What happens if we then place  $m_V = 0$  in the vector field? A standard way to deal with the problem is to replace  $\frac{m_V^2}{2} A_\mu A^\mu \rightarrow -\frac{1}{2\xi} (\partial_\mu A^\mu)^2$ . This effectively uses the Lagrange multiplier technique to fix the Lorenz gauge condition  $\partial_\mu A^\mu = 0$ . What are the Feynman rules if I make this replacement? What if I further specify the gauge by fixing  $\xi = 1$ , where  $\xi$  is a real constant that will be chosen later?
- (d) Using Eq. (1), draw all the Feynman diagrams that would contribute to the  $2 \rightarrow 2$  cross section,  $\psi\bar{\psi} \rightarrow \psi\bar{\psi}$  through order  $g^2$  and  $g^2\lambda_1^2$ .
- (e) Still using Eq. (1), consider the cross section for the  $2 \rightarrow 2$  scattering process  $\psi\psi \rightarrow \psi\psi$ . Start with the general cross section expression derived in class,

$$d\sigma = \frac{|M|^2}{2\sqrt{\lambda(s, m_A^2, m_B^2)}} \frac{d^3\mathbf{p}_1}{(2\pi)^3 2E_1} \cdots \frac{d^3\mathbf{p}_N}{(2\pi)^3 2E_N} (2\pi)^4 \delta\left(k_A + k_B - \sum_{i=1}^N p_i\right), \quad (3)$$

with

$$\lambda(s, m_A^2, m_B^2) = s^2 + m_A^4 + m_B^4 - 2sm_A^2 - 2sm_B^2 - 2m_A^2 m_B^2, \quad (4)$$

and derive the order  $g^2$  expression for the unpolarized differential cross section  $d\sigma/d\Omega|_{\text{CM}}$  in the center-of-mass system. Since it is an unpolarized cross section,

you should sum over the final and average over initial nucleon spins. Let  $p_A$  and  $p_B$  label the initial four-momenta and  $p_C$  and  $p_D$  label the final four-momenta and express your result in terms of Mandelstam variables.

(a) Let us rewrite the Yukawa and vector Lagrangians as follows:

$$\mathcal{L}_Y = \mathcal{L}_{D,\text{sym}} + \mathcal{L}_{KG} - g\bar{\psi}\psi\phi - \frac{\lambda_1}{3!}\phi^3 - \frac{\lambda_2}{4!}\phi^4 \quad (5)$$

$$\mathcal{L}_V = \mathcal{L}_{D,\text{sym}} + \mathcal{L}_P - g\bar{\psi}\not{A}\psi, \quad (6)$$

where  $\mathcal{L}_{D,\text{sym}} = \bar{\psi}(\frac{i}{2}\overleftrightarrow{\not{D}} - M)\psi$  is the free Dirac Lagrangian for spin-1/2 spinor fields,  $\mathcal{L}_{KG} = \frac{1}{2}\partial_\mu\phi\partial^\mu\phi - \frac{m_s^2}{2}\phi^2$  is the free Klein-Gordon Lagrangian for real scalar particles, and  $\mathcal{L}_P = -\frac{1}{4}F^{\mu\nu}F_{\mu\nu} + \frac{m_V^2}{2}A^\mu A_\mu$  is the free Proca Lagrangian for a spin-1 vector particles. The vertices are simple enough to read from the Lagrangian since they are just the coefficients without any factor included for symmetries multiplied by  $i$ . We can determine the propagators easily enough from the mnemonic. For the KG scalar propagator, we list out the steps as follows:

$$D = [(ip_\mu)(-ip^\mu) - m_s^2] = p^2 - m_s^2 \rightarrow D^{-1} = \frac{1}{p^2 - m_s^2 + i\epsilon} \rightarrow \text{Prop} = \frac{i}{p^2 - m_s^2 + i\epsilon}. \quad (7)$$

Similarly, we can determine the Dirac propagator

$$D = \frac{i}{2}\gamma^\mu[(-ip_\mu) - (ip_\mu)] - M = \not{p} - M \rightarrow \text{Prop} = \frac{i}{\not{p} - M} = \frac{i(\not{p} + M)}{p^2 - M^2 + i\epsilon}. \quad (8)$$

For the Proca theory, we must massage the Lagrangian a bit to arrive at a form where we can use the mnemonic properly:

$$\begin{aligned} \mathcal{L}_P &= -\frac{1}{4}(\partial^\mu A^\nu - \partial^\nu A^\mu)(\partial_\mu A_\nu - \partial_\nu A_\mu) + \frac{m_V^2}{2}A^\mu A_\mu \\ &= -\frac{1}{2}(\partial^\mu A^\nu \partial_\mu A_\nu - \partial^\nu A^\mu \partial_\mu A_\nu) + \frac{m_V^2}{2}A^\mu A_\mu \\ &= A^\mu \left[ -\frac{1}{2}(g_{\mu\nu}\overleftrightarrow{\partial}^\rho \partial_\rho - \overleftrightarrow{\partial}_\nu \partial_\mu) + \frac{m_V^2}{2}g_{\mu\nu} \right] A^\nu. \end{aligned} \quad (9)$$

Thus,

$$D_{\mu\nu} = -(p^2 - m_V^2)g_{\mu\nu} + p_\mu p_\nu. \quad (10)$$

Note that the inverse here is not simply the reciprocal, but we have  $D_{\mu\nu}(D^{-1})^{\nu\rho} = \delta_\mu^\rho$ . We can form the inverse as a linear combination of the tensor structures available to us as  $(D^{-1})^{\mu\nu} = Ag^{\mu\nu} + Bp^\mu p^\nu$ , so

$$\begin{aligned} \delta_\rho^\mu &= [-(p^2 - m_V^2)g^{\mu\nu} + p^\mu p^\nu][Ag_{\nu\rho} + Bp_\nu p_\rho] \\ &= [-A(p^2 - m_V^2)\delta_\rho^\mu - B(p^2 - m_V^2)p^\mu p_\rho + Ap^\mu p_\rho + Bp^2 p^\mu p_\rho]. \end{aligned} \quad (11)$$

Because our tensor structures are linearly independent, we have the following equations:

$$\begin{cases} -A(p^2 - m_V^2) = 1 \\ -B(p^2 - m_V^2) + Bp^2 + A = 0. \end{cases} \quad (12)$$

Hence,

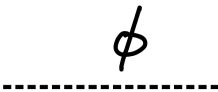

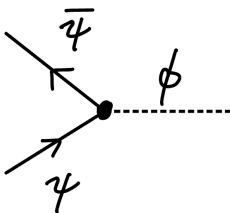

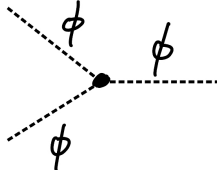

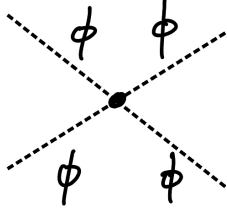

$$A = -\frac{1}{p^2 - m_V^2} \quad (13)$$

$$B = \frac{1}{m_V^2(p^2 - m_V^2)}, \quad (14)$$

and the propagator for a Proca particle is

$$\text{Prop}_{\mu\nu} = \frac{-i(g_{\mu\nu} - p_\mu p_\nu / m_V^2)}{p^2 - m_V^2 + i\epsilon}. \quad (15)$$

Summarizing, the Feynman rules for the Yukawa theory are as follows:

Type	Diagram	Expression
Propagator		$\frac{i}{p^2 - m^2 + i\epsilon}$
Propagator		$\frac{i(\not{p} + M)}{p^2 - M^2 + i\epsilon}$
Vertex		$-ig$
Vertex		$-i\lambda_1$
Vertex		$-i\lambda_2$
